Least Squares Approximation

A general strategy for finding the line $y = mx + b$ that best describes a data set is to find b and m that minimizes the sums of the squares of the vertical distances between the data points and the line, given by $F(b, m)$

$$F(b, m) = \sum_{i=1}^n (y_i - (b + mx_i))^2$$

Least Squares Approximation

A general strategy for finding the line $y = mx + b$ that best describes a data set is to find b and m that minimizes the sums of the squares of the vertical distances between the data points and the line, given by $F(b, m)$

$$F(b, m) = \sum_{i=1}^n (y_i - (b + mx_i))^2$$

To find such a b and m , we need to solve the system:

$$\frac{\partial F}{\partial b} = 0 \quad \text{and} \quad \frac{\partial F}{\partial m} = 0$$
